

5 **A METHOD FOR CHANGING A TARGET ARRAY, A METHOD FOR
ANALYZING A STRUCTURE, AND AN APPARATUS, A STORAGE MEDIUM
AND A TRANSMISSION MEDIUM THEREFOR**

BACKGROUND OF THE INVENTION

10 **Technical Field**

The present invention relates to a method for changing an array, and a method, an apparatus, a storage medium and a transmission medium for analyzing a structure. In particular, the present invention relates to a method for changing an array in order to analyze its structure, a method for employing the array changing method to perform the
15 analyzation of the structure of the array, an array structure analyzation apparatus specifically provided for the employment of the array structure analyzation method, a storage medium on which is stored a program that permits a computer to implement and apply the array structure analyzation method, and a transmission medium for transmitting the program that permits a computer to implement and apply the array structure
20 analyzation method.

Prior Art

Recently, the deciphering of genetic information has been completed for a variety of organisms other than human beings, and it is now anticipated that the same process of
25 explication can be performed for the human genome. For DNA, which is the main component of chromosomes and which is represented by an array of four bases consisting of adenine (A), thymine (T), cytosine (C) and guanine (G), and for RNA, which is transcribed from DNA and which is represented by an array of four bases, in which the T in DNA is replaced by uracil (U), the analyzation of the genetic information is performed
30 by replacing an array of the bases of a single standard DNA or RNA base array with a character string for convenience, extracting from the obtained character string the pattern of a character string that frequently appears, and analyzing the extraction results.

Conventionally, as a technique, a suffix tree (a data structure) is well known that is effective for performing a rapid search of character strings to extract a character string

that appears frequently, or a character string that is common to two or more character strings. The suffix tree represents all the suffixes in a character string wherein the character "\$," which does not exist in a string that is currently being processed, is added at the end of the pertinent character string. An example is the character string "mississippi\$" that, as is shown in Fig. 7, is obtained by adding the character "\$" at the end of "mississippi," the character string that is currently being processed.

As is shown in Fig. 7, a label that corresponds to the character string is provided for each edge of the suffix tree. The first character of each label that is provided for each outgoing edge of one node (including a root node) differs from the others, and the edges are sorted in accordance with the first characters of the labels (for example, in Fig. 7, the edges are arranged in the English alphabetic order from left to right). In the suffix tree, the array of the labels that are provided for the individual edges from the root node to a specific leaf node (a node at the distal end of an edge to which no other edge is connected) is used as a suffix that corresponds to the specific leaf node (for example, "issippi\$" is the suffix that corresponds to the leaf node of the array extending from the edges with labels "ppi\$," "ssi" and "i" to the root node, and "ssissippi\$" is the suffix that corresponds to the leaf node of the array extending from the edges with labels "ssippi\$," "si" and "s" to the root node.

An algorithm is well known whereby the data structure of a suffix tree can be constructed within the time that corresponds to $O(n \log s)$ where n denotes the length (character count) of the original character string, and s denotes the number of types of alphabetic characters that form the original character string). In particular, when the alphabet is an integer alphabet (numerals from 1 to n), the data structure of a suffix tree can be constructed within the time that corresponds to $O(n)$. Therefore, even when a target character string is enormously long, like a character string that represents a DNA or an RNA base array, the data structure of a suffix tree for the pertinent character string can be completed within a short period of time (more specifically, a linear time relative to the length of the original character string). Further, if the suffix tree is employed, a character

string having a length (character count) m can be found in the target character string within a time that corresponds to $O(m \log s)$, so that a character string used in common or a frequently appearing character string can be listed within a short period of time (a linear time relative to the length of the original character string).

5

In addition, when the label provided for each edge is replaced with information that represents the locations of the first character and the last character (character preceding "\$") of the label in the original character string (e.g., "mississippi\$" is replaced with [1•11]), the length of the character string that represents the suffix tree can be fitted to the
10 constant times for the length of the original character string. The suffix array is also well known as a technique by which the length of the character string that represents a suffix tree can be reduced.

As was previously described, leaf nodes of a suffix tree correspond respectively to the
15 suffixes of an original string. When the individual suffixes are arranged beginning with the suffix that corresponds to the leaf node at one end of the suffix tree (the left end in Fig. 7), an array wherein all the suffixes of an original string are arranged in dictionary order is obtained. When the suffixes that are elements of the array are replaced with data that represent the locations of the first characters of the suffixes in the original string
20 (e.g., "ippi\$" is replaced with "8"), an array (called a suffix array) having the same length as the original character string is obtained. For example, the suffix array for "mississippi" in Fig. 7 is "8 5 2 11 1 10 9 7 4 6 3."

When the above suffix array is employed, the memory capacity required for a search for a
25 character string can be reduced compared with when a suffix tree is employed. However, the time required for searching for the character string is $O(m \log n)$, where n denotes the length of a target character string and m denotes the length of a character string that is to be searched for.

A parameterized suffix tree is also well known as a technique (a data structure) for searching for a character string that frequently appears or a character string used in common when the character string includes a variable. For a gene sequence, such as a DNA or RNA base array, a specific element in the array may be exchanged with another specific element (for example, the A and T or the G and C of DNA complement each other and can be exchanged). Thus, in a parameterized suffix tree, when replaceable elements of an array are employed as variables, and when by replacing these variables in character strings (the character strings that include the variables) the character strings can be altered so that they are the same, the character strings are regarded as being the same.

For example, when x, y and z are defined as variables and a, b and c are defined as fixed characters, "axbycxaza" and "azbxczaya" are regarded as being the same character string (called a p-string (Parameterized String)) because by exchanging the variables x, y and z the same character array can be obtained. Encoding that is expressed as prev() is used to detect a p-string. This encoding is used to replace variables in a character string with a numerical value (the first variable that appears is 0) that represents the distance from the same variable that appeared immediately before. When the encoding prev() is performed for the two previously mentioned character strings, prev(axbycxaza) = prev(azbxczaya) = a0b0c4a0a is obtained.

The parameterized suffix tree represents the result that is obtained by performing the prev() encoding for all the suffixes of a character string to which the character \$, which is not present in a target character string, is added (this differs from a normal suffix tree that is prepared while an array obtained by performing the prev() encoding, for a character string to which the character \$ has been added, is regarded as a normal character string). In a parameterized suffix tree, as well as a suffix tree, leaf nodes correspond to the respective suffixes. Each edge has a label that corresponds to a partial character string, and the arrangement of labels that are provided for edges from the root node to a specific leaf node represents the result obtained by the prev() encoding for a suffix that corresponds to the specific leaf node.

Further, in the same manner as for the suffix tree, the first character of each label, which is provided for each edge extending from a node (including the root node), differs the others, and the labels are sorted in accordance with the first character. In addition, since the labels of each of the individual edges are represented by the first and the last positions of the original character string, the data structure has the size of the constant times of length of the character string.

For a gene sequence, such as a DNA or RNA base array, it is well known that although arrays that have the same structure may have different appearances they tend to have the same functions or properties. For a DNA base array, for example, when either or both of the complementary A and T, and the complementary G and C components are exchanged with each other, or when the non-complementary A and C components are exchanged and the non-complementary T and G components are exchanged, the structure of the array (the relationship of the elements of the array) tends to be unchanged, even though the array differs from the original array, and the functions and the properties obtained by effecting the exchange tend to be similar to those of the original array. Therefore, when analyzing a gene sequence, it is extremely important that arrays having the same structure be defined as the same array, regardless of whether the array themselves are identical, and that a frequently appearing array be extracted or that a partial array commonly included in two arrays be searched for.

On the other hand, with the conventional technique for employing a suffix tree or a suffix array, a character string other than an identical one can not be defined as being the same character string, so that even though an array may have the same structure, if it has a different element arrangement it can not be treated as the same array. Further, in a parameterized suffix tree, a character string wherein variables are simply replaced is defined as being the same character string. Thus, when, for example, only A and C are exchanged in the DNA base array, or only T and G are exchanged, or when A is exchanged with C and T with A, an array having a different structure from the original array can not be distinguished from an array having the same structure as the original

array. Therefore, even when any of the above conventional techniques is employed, it is difficult to efficiently analyze a gene sequence.

To resolve the above shortcomings, it is one object of the present invention to provide a method for changing an array in order to efficiently analyze the structure of the array.

It is another object of the present invention to provide a method, an apparatus, a storage medium and a transmission medium for efficiently analyzing the structure of an array.

10 **Summary of the Invention**

To achieve the above objects, according to the present invention, a method for changing an array comprises the steps of: changing a variable in a target array to information that represents the location of a different variable when the target array, consisting of a combination of a plurality of various kinds of elements (all of the elements may be variables that can be replaced by other elements, or elements other than the variables may be included) is viewed along a path extending in a predetermined direction (e.g., a path extending from either end of the target array to the other end), and when a different, complementary variable is present upstream of a variable included in the target array; changing the variable to information indicating that no different, complementary variable is present when no different, complementary variable is present upstream of the variable in the target array; and repeating the steps for all the other variables included in the target array.

Through the change, the complementary variables in the array are altered to provide information that represents the positional relationships of the variables (information indicating the presence/absence of the variables as well as their locations). Thus, from an array that has a plurality of complementary variable pairs, the array changing method of the present invention produces an equivalent array (i.e., the structure of the array (the relationships of the elements of the array) is the same, even though the array itself is

different) by exchanging certain of the variables in the different complementary variable pairs.

As an example, when the variable x and the variable z are complementary, and the variable y and the variable w are complementary, the array changing method of the invention (hereinafter referred to as compl()) is used to change the array (ABxByAzww) as follows:

compl(ABxByAzww) = AB0B0A436.

The "0"s in the obtained array indicate that complementary variables are not present upstream, and the "4," the "3" and the "6" are used to represent distances to those complementary variables that are present upstream.

The array changing method of the present invention is employed to (1) change an array (ABzByAxwx) wherein only the complementary variables x and z are exchanged, (2) change an array (ABxBwAzyz) wherein only the complementary variables y and w are exchanged, and (3) change an array (ABwBzAyxy) wherein the variables x and w that are not complementary and the variables y and z that are not complementary are exchanged, so that all of the arrays have the same structure as the original array. The obtained arrays are:

- (1) compl(ABzByAxwx) = AB0B0A436
 - (2) compl(ABxBwAzyz) = AB0B0A436
 - (3) compl(ABwBzAyxy) = AB0B0A436
- and are equivalent to the original array.

The array changing method of the present invention is employed to change an array (ABwByAzxz) wherein only the variables x and w that are not complementary are exchanged, which provides an array that has a structure different from that of the original array. The obtained array is

compl(ABwByAzxz) = AB0B2A011

and thus is different from the original array.

As is apparent from above, when one pair of arrays are changed using the array changing method of the invention, the resultant arrays can be compared to efficiently determine whether the structures of the array pairs are identical, or to determine whether a sequence having the same structure is included in both the arrays. When a specific array is changed using the method of the invention, the resultant array can also be employed to easily extract a sequence having the same structure that appears frequently in the array. Therefore, according to the array changing method of the invention, the structure of an array can be changed so that an efficient analyzation of the structure of the array can be performed.

According to the array changing method of the invention, arrays having the same structure can be changed to equivalent arrays; however, although very rare, there are exceptional cases in which arrays having different structures are changed into equivalent arrays. For example, in the DNA base array, the array (TTAA) and the array (AGCC), which differ in structure, are changed by the array changing method of the invention. The resultant arrays are $\text{compl}(\text{TTAA}) = \text{compl}(\text{AGCC}) = (0012)$, which are equivalent.

According to the present invention, a method for analyzing the structure of an array comprises the steps of: changing a variable that is included in a target array consisting of a combination of a plurality of different kinds of elements and that is replaceable with another element into information representing the location of the same variable when the target array is viewed along a path extending in a predetermined direction, and when the same variable is present upstream of the variable; and changing, when the same variable is not present upstream of the replaceable variable in the target array, all the variables in the target array into information indicating that the same variable is not present, and thus changing the target array into a first array.

By changing the target array to a first array, the variables in the target array are converted to data (data that represent the presence/absence of the same variable and its location) that represents the positional relationship of the same variable in the array. Thus, one pair of arrays that have different structures but are changed to equivalent arrays by the method of the invention can be changed as first arrays that differ from each other. For example, the arrays (TTAA) and (AGCC), which are to be changed to equivalent arrays by the array changing method of the invention, are changed to the following first arrays that differ from each other:

prev(TTAA) = (0101) prev(AGCC) = (0001)

- 10 The "0"s in the obtained first array indicate that the same variables are not present upstream, and the "1"s represent distances to the same variables that are present upstream.

- 15 According to the method for analyzing the structure of an array, in the above manner, the target array is changed to the first array and is also changed to a second array by the array changing method of the present invention, and the first and the second arrays are employed to analyze the structure of the target array. Thus, the array for which the first and the second arrays obtained by the process are equivalent is determined to be the same array, so that the array having a different structure can be excluded and only the array having the same structure can be precisely identified. As a result, the structure of the array can be efficiently analyzed.

- 25 Various analyzation methods are available for employing the first and the second arrays to analyze the structure of the array. As an example method, a suffix tree is prepared by using the first and the second arrays and is employed to analyze the structure of the array. This method is preferable because the process can be completed within a shorter time than can the other analyzation methods. To prepare the suffix tree, for example, in an operation to prepare a single suffix tree the first and the second arrays are regarded as a single pair of corresponding character strings. Then, from among sequences of the first and the second arrays, which are provided as labels for individual edges of the single

target array, which is one type of process used for the analyzation of the structure of the target array.

Further, when searching for a common sequence in a first target array and a second target array, which is one type of process used for the analyzation of the structure of a target array, a suffix tree is prepared by using, as the target array (an array for which suffixes are to be prepared), an array wherein the first target array, first identification information, the second target array and second identification information are arranged in order. Then, when the thus prepared suffix tree is employed, it is extremely easy to search for the common sequence.

The suffix tree employs a tree structure to represent all the suffixes that are present in a character string when the character string is viewed along a path extending in a specific direction. The suffix in the character string is a prefix as viewed from the opposite direction. While taking into account the analyzation of the structure of the array, a prefix tree that employs a tree structure to represent all the prefixes in the character string is also logically equivalent to the suffix tree. Therefore, instead of the suffix tree, the prefix tree may be employed for this invention.

According to the present invention, an apparatus for analyzing the structure of an array comprises: first conversion means for changing a target array into a first array by converting, in the target array, a variable that is replaceable by another element into information indicating the position of the same variable or information indicating the absence of the same variable; second conversion means for changing the target array into a second array by converting, in the target array, a variable that is replaceable by another element into information indicating the position of a different, complementary variable, or information indicating the absence of the different, complementary variable; and analyzation means for employing the first and the second arrays to analyze the structure of the target array. With this apparatus, as well as by applying the method of the

invention for analyzing the structure of the array, the structure of the array can be efficiently analyzed.

According to the present invention, a storage medium is provided on which is stored a
5 program that permits a computer to implement the method of the invention to analyze the
structure of an array, i.e., that permits a computer to perform the processing comprising: a
first step of changing a target array into a first array by converting, in the target array, a
variable that is replaceable by another element into information indicating the position of
the same variable or information indicating the absence of the same variable; a second
10 step of changing the target array into a second array by converting, in the target array, a
variable that is replaceable by another element into information indicating the position of
a different, complementary variable, or information indicating the absence of the
different, complementary variable; and a third step of employing the first and the second
arrays to analyze the structure of the target array. With this apparatus, as well as by
15 applying the method of the invention for analyzing the structure of the array, the structure
of the array can be efficiently analyzed. Since the computer reads the program from the
storage medium and executes it, the structure of the array can be efficiently analyzed in
the same manner as in the method of the invention used for analyzing the structure of the
array.

20
According to the present invention, a transmission medium is provided for transmitting a
program that permits a computer to perform the method of the invention by analyzing the
structure of an array, i.e., a program that permits a computer to perform the processing
comprising: a first step of changing a target array into a first array by converting, in the
25 target array, a variable that is replaceable by another element into information indicating
the position of the same variable or information indicating the absence of the same
variable; a second step of changing the target array into a second array by converting, in
the target array, a variable that is replaceable by another element into information
indicating the position of a different, complementary variable, or information indicating
30 the absence of the different, complementary variable; and a third step of employing the

first and the second arrays to analyze the structure of the target array. With this apparatus, as well as by applying the method of the invention for analyzing the structure of the array, the structure of the array can be efficiently analyzed. Therefore, when the computer uses storage means to temporarily store the program received from the transmission medium, and then reads the program from the storage means and executes it, the structure of the array can be efficiently analyzed in the same manner as it is when the method of the invention is used that is specifically provided for the analyzation of the array structure.

10 **Brief Description of the Drawings**

Preferred embodiments of the present invention will now be described, by way of example only, with reference to the accompanying drawings in which:

Fig. 1 is a schematic block diagram illustrating the arrangement of a computer system according to one embodiment of the present invention.

15 Fig. 2 is a flowchart showing the structure suffix tree generation processing according to the embodiment of the present invention.

Fig. 3 is a flowchart showing the prev () calculation processing.

Fig. 4 is a flowchart showing the compl () calculation processing.

Fig. 5 is a flowchart showing the structure suffix tree generation processing.

20 Figs. 6A to 6H are conceptual diagrams showing example processing for preparing a structure suffix tree according to the embodiment.

Fig. 7 is a conceptual diagram showing an example suffix tree.

Detailed Description of the Preferred Embodiments of the Invention

25 The preferred embodiment of the present invention will now be described in detail while referring to the drawings.

Fig. 1 is a specific diagram illustrating, for each sub-system, the hardware arrangement of a computer system 10 comprising a personal computer (PC) that is appropriate for the present invention. An example PC for carrying out the present invention is either a

notebook or a desktop PC that conforms to the OADG (PC Open Architecture Developer's Group) specifications, and on which is mounted, as an operating system (OS), "Windows98" or "NT," by Microsoft Corp., or "OS/2," by IBM. The individual sections of the computer system 10 will now be described.

5

A CPU 14, which is the brain of the entire computer system 10, executes various programs under the control of the OS. The CPU 14 may, for example, be a "Pentium," "MMX technology Pentium" or "Pentium Pro" by Intel Corp., a "Power PC" by IBM, or a CPU by another maker, such as AMD Corp. The CPU 14 includes an L2 (level 2)-cache, which is fast operating memory, for temporarily storing very limited code or data that are frequently accessed so as to reduce the total time required to access a main memory 16. The L2-cache is generally constituted by an SRAM (Static RAM) chip that has a memory capacity of at least 512 kB.

10

15 The CPU 14 is connected to the individual hardware components, which will be described later, via three bus layers, including: an FSB 18, which is a processor bus directly connected to the external pin of the CPU 14; a PCI (Peripheral Component Interconnect) bus 20, which is a fast I/O bus; and an I/O bus 22, which is an ISA (Industry Standard Architecture) bus for low speed I/O.

20

The FSB 18 and the PCI bus 20 are generally connected by a bridge circuit (host-PCI bridge) that is called a memory/PCI control chip 24. In this embodiment, the memory/PCI control chip 24 includes a memory controller function for controlling the access to the main memory 16 and a data buffer for absorbing the difference in data transmission speeds between the FSB 18 and the PCI bus 20. A 440EX or a 440GX by Intel Corp. can be employed as the memory/PCI control ship 24.

25

The main memory 16 is a writable area that is used as a reading area for a program for the CPU 14, or as a work area for writing data processed by the program. The main memory 16 is generally constituted by a plurality of DRAM (Dynamic RAM) chips. As

30

a standard, 32 MB of memory is mounted, but this can be expanded to 256 MB. Recently, in order to respond to requests for high-speed processing, DRAM has been exchanged for fast page DRAM, EDO DRAM, synchronous DRAM (SDRAM), burst EDO DRAM, or RDRAM.

5

The programs herein include firmware, such as the OS, represented by Windows98, various device drivers for operating peripheral devices, application programs for specific jobs, and a BIOS (a Basic Input/Output System: a program for controlling the input/output operation of hardware components, such as keyboards and floppy disk drives) that is stored in a flash ROM 56 (which will be described in detail later).

10

The PCI bus 20 is a bus for comparatively rapid data transmission (e.g., a bus width of 32/64 bits, with a maximum operating frequency of 33/66/100 MHz and a maximum data transmission speed of 132/264 MBps). The PCI bus 20 is connected to a PCI device, such as a card bus controller 30, that is driven at a comparatively high speed. It should be noted that the PCI architecture originally was advocated by Intel Corp., and that a so-called PnP (Plug and Play) function is provided and employed.

15

A video sub-system 26, which includes a video controller, performs a video associated function. Actually, the video controller handles drawing commands received from the CPU 14, temporarily writes obtained drawing data in a video memory (VRAM), and reads the drawing data from the VRAM and outputs it to a liquid crystal display (LCD). The video controller also employs an attached digital-analog converter (DAC) to convert digital video signals to analog video signals. The analog video signals are output via a signal line to a CRT port (not shown).

20

25

The PCI bus 20 is also connected to the card bus controller 30, an audio sub-system 32 and a modem sub-system 34. The card bus controller 30 is a special controller for directly transmitting a bus signal carried by the PCI bus 20 to the interface connector (card bus) of a PCI card bus slot 36. The card bus slot 36 is formed, for example, in the

30

wall of the main body of the PC, and a PC card (not shown) that conforms to the standards (e.g., "PC Card Standard 95") determined by the PCMCIA (Personal Computer Memory Association)/JEIDA (Japan Electronic Industry Development Association) is loaded into the card bus slot 36.

5

Connected to the modem sub-system 34 is a communication line, such as a LAN line or a telephone line, that can be used to connect the computer system 10 to the Internet.

10 The PCI bus 20 and the I/O bus 22 are interconnected by a multi-functional PCI device 38. The multi-functional PCI device 38 includes a function for bridging the PCI bus 20 and the I/O bus 22, a DMA controller function, a programmable interrupt controller (PIC) function, a programmable interval timer (PIT) function, an IDE (Integrated Drive Electronics) interface function, a USB (Universal Serial Bus) function and an SMB (System Management bus) interface function. A PIIX4, for example, by Intel Corp. can
15 be used as the multi-functional PCI device 38.

The DMA controller function transmits data between a peripheral device (e.g., an FDD) and the main memory 16, without the CPU 14 being required. The PIC function executes a predetermined program (an interrupt handler) in response to an interrupt request (IRQ)
20 received from a peripheral device. And the PIT function, which has a programmable generation cycle, generates a timer signal each predetermined cycle.

An IDE interface, which is implemented by the IDE interface function, is used to connect to an IDE hard disk drive (HDD) 40, and ATAPI (AT Attachment Packet Interface) is
25 used to connect an IDE CD-ROM drive 42, or may instead be used to connect another type of IDE device, such as a DVD (a Digital Video Disc or a Digital Versatile Disc) drive. External devices, such as the HDD 40 and the CD-ROM drive 42, are stored in locations called "media bays" or "device bays." The external storage devices that are mounted as standard may be so provided that they can or can not be replaced by other
30 devices, such as FDDs or battery packs.

The main memory 16 corresponds to a main storage device for the present invention, and the HDD 40 corresponds to a secondary storage device for the present invention.

- 5 A USB port is provided for the multi-functional PCI device 38, and is connected to a USB connector 44 that is provided, for example, on the wall of the PC main body. The USB supports a function (a hot plugging function) for the insertion and removal of peripheral devices (USB devices) while the power is on, and a function (a plug and play function) for automatically recognizing a newly connected peripheral device and for
10 resetting the system configuration. A maximum of 63 USB devices can be daisy-chain connected to one USB port. Example USB devices are a keyboard, a mouse, a joy stick, a scanner, a printer, a modem, a display monitor and a tablet.

- In addition, an EEPROM (not shown) is connected via an SM bus to the multi-functional
15 PCI device 38. The EEPROM is a nonvolatile, electrically rewritable memory for storing information, such as a password that is registered by a user, a supervisor password and a product serial number.

- The I/O bus 22 has a lower data transmission speed than the PCI bus 20 (e.g., a bus width
20 of 16 bits and a maximum data transmission speed of 4 MBps). Connected to the I/O bus 22 are a Super I/O controller 46, a power controller 48, the flash memory 56 consisting of an EEPROM, CMOS RAM 58, and a peripheral device (not shown) such as a real time clock (RTC) or a keyboard/mouse controller that is operated at a comparatively low speed.

- 25 Connected to the Super I/O controller 46 is an I/O port 52 that serves as a peripheral controller for driving a floppy disk drive (FDD), for controlling the input/output (PIO) of parallel data via a parallel connection and the input/output (SIO) of serial data via a serial connection.

30

The power controller 48 is mainly used to control the power management or the thermal management of the computer system 10, and can be constituted by a single-chip micro computer that includes an MPU, a RAM, a ROM and a timer. In the ROM are stored a program and a reference table that are required to execute the power management and the thermal management functions. The power controller 48, which is connected to a power supply controller 54, includes a charger for charging a battery and a DC/DC converter for generating a constant DC voltage, such as 5 V or 3.3 V, that is used by the computer system 10. The supply of power by the controller 54 is controlled by the power controller 48.

The flash ROM 56 is composed of nonvolatile memory used to store a firmware program, such as the BIOS or boot strap code, and the contents stored therein can be electrically rewritten. The CMOS RAM 58, which is provided by connecting a semiconductor memory to a backup power source, functions as nonvolatile, fast storage means.

Many electric circuits in addition to those in Fig. 1 are required to constitute the computer system 10. However, since these are well known to one having ordinary skill in the art, and since those electric circuits are not directly related to the subject of the invention, no further explanation will be given for them in this specification. Furthermore, to avoid complexity in the drawings, only a part of the connections for the hardware blocks in Fig. 1 are shown.

The processing for the invention will now be described. A method for changing an array and a method for analyzing the structure of an array of the present invention will be implemented by a program for analyzing the structure of an array. Several methods are used to install the structure analyzation program into the computer system 10. For example, to install the structure analyzation program a setup program, along with the structure analyzation program, is stored on a data storage medium 60 (see Fig. 1), such as a floppy disk. The data storage medium 60 is inserted into an FDD that is connected to an I/O port 52 in the computer system 10, and an instruction is issued to the CPU 14 to

execute the setup program. Following this, the structure analyzation program is installed by being sequentially read from the data storage medium 60 and written on the HDD 40.

When an instruction for the generation of a suffix tree is issued to a computer system 10 that has been powered on and is ready to operate, the CPU 14 reads the structure analyzation program from the HDD 40 and executes it. Thus, the computer system 10 functions as an apparatus according to the present invention for analyzing the structure of an array. As is apparent from the above description, the data storage medium 60 corresponds to a storage medium according to the present invention.

While referring to the flowchart in Fig. 2, an explanation will be given for the suffix tree generation processing performed when the CPU 14 executes a suffix tree generation program, which is one part of the structure analyzation program.

At step 100 a character string S (a target array) to be processed (to be analyzed) is fetched. The target character string S can be a character string that represents a single-stranded DNA base array by replacing the four bases (adenine, thymine, cytosine and guanine) with four characters, "A," "T," "C" and "G" respectively, or a character string that represents an RNA base array by replacing four bases (adenine, uracil, cytosine and guanine) with characters "A," "U," "C" and "G". An end identification character (a character, such as "\$," that is not present in a character string) that is used to identify a character string end, is added to the character string S that is fetched at step 100.

Hereinafter, the i-th character of the character string S is denoted by S[i], a character string part that begins with the j-th character of the character string S and ends with i-th character is denoted by S[j..i], and the length of the character string S (the character count) is denoted by n (i.e., S[1..n] = the character string S).

At step 102, the character string S is changed to a first character string S1 in accordance with a changing condition prev() (prev(S) = S1), and is also changed to a second

character string S2 in accordance with a changing condition compl(). The conversion of the character string S into the first character string S1 can be performed by the prev() calculation process in Fig. 3, for example. The prev() calculation process corresponds to the conversion to the first array for which the structure analyzation method is used. This process will now be described.

At step 130, "0"s are set for character position registers X_1, X_2, \dots . The character position registers are provided in a number equivalent to the types of variables that are included in the character string S (variables here are characters that are replaceable with other characters (variables) during the analyzation of the structure of the character string S: e.g., "A," "T," "C" and "G" for the character string that represents the single-stranded DNA base array, and "A," "U," "C" and "G" for the character string that represents the RNA base array.) At step 132, "1" is substituted into a counter i.

At step 134, the i-th character $S[i]$ is extracted from the character string S, and at step 136, a check is performed to determine whether the character $S[i]$ is a variable. When it is determined that the character $S[i]$ is not a variable (for example, when the character string S represents the DNA or RNA base array and the character $S[i]$ is an end identification character, or when the character string S also includes characters other than variables and the character $S[i]$ represents an entry other than a variable), program control is shifted to step 138. The character $S[i]$ is stored as the i-th character of the first character string S, and program control is shifted to step 150.

When the character $S[i]$ is a variable, the decision at step 136 is affirmative, and program control advances to step 140, whereat a variable type α of the character (variable) $S[i]$ is examined. At step 142, a check is performed to determine whether a numerical value of "0" has been set for a character position register X_α that corresponds to the variable type α of the character (variable) $S[i]$. When a numerical value of "0" has been set for the character position register X_α , it is assumed that the character $S[i]$ is a variable of a

variable type α that appears first, and that the same variable (a variable of the same variable type α) is not present upstream of the character $S[i]$ in the character string S .

When the decision at step 142 is affirmative, program control is shifted to step 144. A
5 value of "0" (information indicating that the same variable is not present upstream of the character $S[i]$ in the character string S) is stored as the i -th character of the first character string $S1$. Program control is then shifted to step 148. At step 148, the value of the counter i (information that represents the position of the character $S[i]$ of the character string S) is substituted into the character position register $X\alpha$. Therefore, when a variable
10 of the variable type α appears next, an affirmative decision is obtained at step 142.

At step 152, a check is performed to determine whether the value of the counter i matches the length (the character count) n of the character string S . When the decision at step 152
15 is negative, the value of the counter i is incremented by one. Program control then returns to step 134, the next character is extracted as the character $S[i]$, and the processing following step 136 is repeated.

When the character $S[i]$ is a variable and a like variable appeared previously, the decision at step 136 is affirmative, the decision at step 142 is negative, and program control
20 advances to step 146. At step 146, " $i-X\alpha$ " is stored as the i -th character of the first character string $S1$, and program control advances to step 148. At this time, since the position in the character string S of the variable that appeared previously, which is the same as that represented by the character $S[i]$, is stored in the character position register $X\alpha$, " $i-X\alpha$ " constitutes numerical information that indicates the upstream position,
25 relative to the character $S[i]$, in the character string S of the previously stored variable (more specifically, information that indicates the distance from the character $S[i]$ to a like variable that appeared previously).

Through the `prev()` calculation process, when upstream in a character string S a like
30 variable or like variables are present, a variable downstream of a like variable that

appeared previously is converted into a numerical value representing the distance to the variable that appeared previously. When there is no like upstream variable, a variable in the character string S is changed to "0." Thus, for example, the character string S(AUAUCGU\$), which represents an RNA base array, is changed to the following first
5 character string S1.

prev(AUAUCGU\$) = S1 = (0022003\$)

In addition, the conversion of the target string S into a second character string S2 can be performed using the compl() calculation process in Fig. 4. The compl() calculation
10 process corresponds to the conversion to the second array by the array changing method and the structure analyzation method of the present invention. The compl() calculation process will now be described.

In the compl() calculation process, a pair of complementary variables are determined in
15 advance for a variable included in the character string S. For example, for a character string S that represents the single-stranded DNA base array, two pairs of complementary variables, A and T, and C and G, are determined in advance, based on the actual relationship existing between the individual bases in the DNA base array. For a character string S that represents the RNA base array, two pairs of complementary variables, A and
20 U, and C and G are determined in advance based on the actual relationship of the individual bases in the RNA base array.

At step 160, a value "0" is set for the character position registers X_1, X_2, \dots , and at step 162 a value "1" is substituted into the counter i. At step 164, the i-th character $S[i]$ is
25 extracted from the character S, and at step 166 a check is performed to determine whether the character $S[i]$ is a variable or not. When the decision at step 166 is negative, program control is shifted to step 168, whereat the character $S[i]$ is stored as the i-th character of the second character string S2. Program control is then shifted to step 180.

When the character $S[i]$ is a variable, the decision at step 166 is affirmative, and program control advances to step 170. The variable type α of the character (variable) $S[i]$ is examined, and the variable type β , which is the complementary variable of the variable type α , is examined (in this case, if the character $S[i]$ is "A," "T," "C" or "G," respectively, the type β of "T," "A," "G" or "C" is examined). At step 172, a check is performed to determine whether a numerical value of "0" has been set for the character position register $X\beta$ for the variable type β that is the complementary of the character (variable) $S[i]$. If the character position register $X\beta$ has been set for the numerical value of "0," it is assumed that a variable of the variable type β has not yet appeared, and that a different variable (a variable of variable type β), the complementary variable of the character $S[i]$ of the character string S , is not present upstream of the character $S[i]$.

Therefore, when the decision at step 172 is affirmative, program control is shifted to step 174. A value of "0" (information indicating that a different, complementary variable is not present upstream of the character $S[i]$ in the character string S) is stored as the i -th character of the second character string $S2$. Program control is thus shifted to step 178. At step 178, the value of the counter i (information indicating the position of the character $S[i]$ of the character S) is substituted into the character position register $X\alpha$. Thus, when a variable of a complementary variable type β appears next, the affirmative decision is obtained at step 172.

At step 182, the a check is performed to determine whether the value of the counter i matches the length (character count) n of the character string S . When the decision is negative, at step 182, the value of the counter i is incremented by one, and program control returns to step 164, whereat the character $S[i]$ is extracted. Thereafter, the processing following step 166 is repeated.

When the character $S[i]$ is a variable and when a different complementary variable of the character $S[i]$ appeared previously, the decision at step 166 is affirmative, the decision at step 172 is negative, and program control advances to step 176. At step 176, " $i-X\beta$ " is

stored as the i -th character of the second character string $S2$, and program control advances to step 178. At this time, since the position in the character string S of the different complementary variable of the character (variable) $S[i]$ that appeared previously is stored in the character position register $X\beta$, " $i-X\beta$ " is numerical information indicating the position in the character string S of the different complementary variable of the character $S[i]$ that is present upstream of the character $S[i]$ (more specifically, numerical information that represents the distance from the character $S[i]$ to the complementary variable that appeared previously).

- 10 Through the above described $\text{compl}()$ calculation processing, when a complementary variable or variables are present upstream of variables in the character string S , all the variables in the character string S are changed to numerical values, each of which represents the distance to a complementary variable. However, when a complementary variable is not present upstream of a variable, the specific variable is changed to "0."
- 15 Thus, for example, the character string $S(\text{AUAUCGU\$})$, which represents the RNA base array, is changed to the following second character string $S2$.
- $\text{compl}(\text{AUAUCGU\$}) = S2 = (0111014\$)$

- When the target character string S has been changed to the first character string $S1$ and the second character string $S2$, program control is shifted to step 104 in the flowchart in Fig. 2. At step 104 and the following steps, the first character string $S1$ and the second character string $S2$ are regarded as a pair of corresponding character strings, and are employed to generate a single suffix tree (referred to as a structure suffix tree). A label that corresponds to a portion of a character string in the first character string $S1$ and a label that corresponds to the second character string $S2$ are provided for the individual edges of the structure suffix tree that is generated below.

- Further, in the following explanation, $\text{label}(V)$ denotes a label string (character string) that is obtained by coupling labels that are provided for all the edges along the path extending from a node V to a root node V_{root} . $V(\dots)$ denotes a node having " \dots " as a label ($\text{label}(V) = \dots$). $V(\phi)$ denotes the root node V_{root} , and $E(\dots)$ denotes an edge

between the node V, whereat the character string "..." is the suffix for label (V), and the parent node of the node V. $f(\dots)$ denotes a function for replacing the k-th (k is an arbitrary integer) character (numerical value) of character string (...) with "0" when the k-th character is a value equal to or greater than k.

5

First, at step 104, "1"s are substituted into the counters i and j, and at step 106, the root node Vroot of the structure suffix tree is prepared. At step 108, the root node Vroot is substituted into a parameter s, which is used to point to a node that corresponds to a search start position whereat, for a search, tracing of the structure suffix tree is initiated.

10 And ϕ (empty set) is substituted into a temporary t, for temporarily storing the information, and the root node Vroot is substituted into an area sL(Vroot), which is used to point to a specific node.

In the structure suffix tree, the area sL() is an area that is provided while corresponding to each of the nodes except for the leaf nodes. In the area sL(V) of the node V, either
15 information indicating a node W, for which label(W) is a character string obtained by removing the first character from label(V) (i.e., $sL(V) = W$), or information indicating a parent node of an edge, wherein the node W seems to be present, is set, which will be described later. Since label(Vroot) = ϕ , sL(Vroot) b Vroot is defined for the convenience
20 sake.

At step 110, a check is performed to determine whether the value of the counter i is greater than the character count n of the target character string S. When the decision is negative, at step 112 the structure suffix tree generation process is performed, which will
25 be described later. After the structure suffix tree generation process has been performed, at step 114 the value of the counter i is incremented by one, and program control returns to step 110. Therefore, during a period continuing until $i > n$ is established, the structure suffix tree generation process is repeated while the value of the counter i is incremented.

The structure suffix tree generation process at step 112 will now be described while referring to the flowchart in Fig. 5. To make the process easier to understand, (AUAUCGUAUA\$) is employed as the target character string S (i.e., the first character string $S1 = (0022003\$)$ and the second character string $S2 = (0111014\$)$). However, in the structure suffix tree generation process, the structure suffix tree for an arbitrary character string can be generated.

At step 200, the structure suffix tree is traced beginning at a node s (the root node V_{root} at first) and moving toward a leaf node to search for an edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$. Since $S1[j..i-1]$ and $S2[j..i-1]$, for example, are both ϕ when $i = j = 1$, $f(S1[j..i-1])$ and $f(S2[j..i-1])$ are also ϕ . At this time, since a node other than the root node V_{root} and an edge are not present along the structure suffix tree, the edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is not found.

At step 202, a check is performed to determine whether an edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is present. When, for example, $i = j = 1$, and $S1 = (0022003\$)$ and $S2 = (0111014\$)$, $S1[j..i] = S1[1] = (0)$ and $S2[j..i] = S2[1] = (0)$, so that $f(S1[j..i]) = (0)$ and $f(S2[j..i]) = (0)$ are obtained. At this time, since a node other than the root node V_{root} and an edge are not present along the structure suffix tree, the decision at step 202 is negative. And when the decision at step 202 is negative, program control advances to step 204 and a check is performed to determine whether a node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is present. If $i = j = 1$, $f(S1[j..i-1])$ and $f(S2[j..i-1])$ are both ϕ , as was previously remarked. However, since $V(\phi)$ represents V_{root} , the decision at step 204 is affirmative, and program control is shifted to step 206. At step 206, "NO" is substituted into flag node#constructed, and program control is thereafter shifted to step 212.

At step 212, a check is performed to determine whether the temporary t is ϕ . Since the temporary t is initially set to ϕ at step 108 (Fig. 2), the decision at step 212 is affirmative, and program control is shifted to step 218, whereat a check is performed to determine

whether the flag node#constructed indicates "YES." Since at step 206 "NO" was substituted into the flag node#constructed, the decision at step 218 is negative, and program control is shifted to step 220. A node that is designated by the area sL() of the node (the root node Vroot in this case) of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is substituted into the parameter s. Since at step 108 Vroot was substituted into the sL(Vroot), the root node Vroot is substituted into the parameter s. When the process at step 200 is performed next, the search is initiated beginning at the node that is stored in the parameter s.

Program control is then shifted from step 220 to step 226. At step 226, a child node is prepared for the node (the root node Vroot in this case) of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$, and labels obtained by removing $f(S1[j..i-1])$ from $f(S1[j..])$ and by removing $f(S2[j..i-1])$ from $f(S2[j..])$ are provided for an edge from the prepared child node. Therefore, as is shown in Fig. 6A, the child node (leaf node) is generated for the root node, and labels that are obtained by removing $f(S1[j..i-1])$ from $f(S1[j..])$ (since $f(S1[j..i-1]) = \phi$, label (0022003\$)) and by removing $f(S2[j..i-1])$ from $f(S2[j..])$ (since $f(S2[j..i-1]) = \phi$, label (0111014\$)) are provided for an edge (edge labeled A).

At step 228, the value of the counter j is incremented by one, and at step 230, the value of the counter j is greater than the value of the counter i. Since $i (= 1) < j (= 2)$, the decision at step 230 is affirmative, and the structure suffix tree generation process is temporarily halted. When the counter i is incremented by one (step 114 in Fig. 2), the structure suffix tree generation process is resumed under the condition wherein $i = j = 2$.

Since $S1[j..i-1]$ and $S2[j..i-1]$ are both ϕ when $i = j = 2$, $f(S1[j..i-1])$ and $f(S2[j..i-1])$ are both ϕ and the edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ are ϕ . Since $f(S1[j..i]) = f(S1[2]) = (0)$ and $f(S2[j..i]) = f(S2[2]) = (0)$, the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is present (edge A). Therefore, the decision at step 202 is affirmative, and program control is shifted to step 232. Then, the parent node (the root node Vroot in this case) of the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is substituted into the parameter s. At step 234, a check is performed to determine whether the temporary t is ϕ . In this case, the decision at step

234 is affirmative, and the structure suffix tree generation process is temporarily halted. When the value of the counter i is incremented by one, the structure suffix tree generation process is resumed under the condition wherein $i = 3$ and $j = 2$.

- 5 Since, with $i = 3$ and $j = 2$, $f(S1[j..i-1]) = f(S1[2]) = (0)$ and $f(S2[j..i-1]) = f(S2[2]) = (0)$, at step 200 the edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is found (edge A). Further, since $f(S1[j..i]) = f(S1[2..3]) = (00)$ and $f(S2[j..i]) = f(S2[2..3]) = (01)$, the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is also found (edge A). Therefore, the decision at step 202 is again affirmative, and program control is shifted to step 232, whereat the parent node
- 10 (the root node Vroot) of the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is substituted into the parameter s . When the process at step 200 is performed the next time, the search is initiated beginning at the node that is stored in the parameter s . In addition, since the temporary t is ϕ , the decision at step 234 is affirmative, and the structure suffix tree generation process is temporarily terminated. When the value of the counter i is
- 15 incremented, the structure suffix tree generation process is resumed under the condition wherein $i = 4$ and $j = 2$.

- Since, with $i = 4$ and $j = 2$, $f(S1[j..i-1]) = f(S1[2..3]) = (00)$ and $f(S2[j..i-1]) = f(S2[2..3]) = (01)$, at step 200 the edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is found (edge A).
- 20 Further, since $f(S1[j..i]) = f(S1[2..4]) = (002)$ and $f(S2[j..i]) = f(S2[2..4]) = (011)$, the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is also present (edge A). Therefore, the decision at step 202 is again affirmative, and program control is shifted to step 232. The parent node (root node Vroot) of the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is substituted into the parameter s . When the process at step 200 is performed next, the search is initiated
- 25 beginning at the node that is stored in the parameter s . Furthermore, since the temporary t is ϕ , the decision at step 234 is affirmative, and the structure suffix tree generation process is temporarily terminated. When the value of the counter i is incremented, the structure suffix tree generation process is resumed under the condition wherein $i = 5$ and $j = 2$.

30

Since, with $i = 5$ and $j = 2$, $f(S1[j..i-1]) = f(S1[2..4]) = (002)$ and $f(S2[j..i-1]) = f(S2[2..4]) = (011)$, at step 200 the edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is found (edge A). In addition, since $f(S1[j..i]) = f(S1[2..5]) = (0020)$ and $f(S2[j..i]) = f(S2[2..5]) = (0110)$, the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i])) = \phi$ and the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1])) = \phi$. The decisions at steps 202 and 204 are negative, and program control is shifted to step 208.

At step 208, the edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ (edge A in this case) is divided based on the search results obtained at step 200, and a node that corresponds to $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is generated. Thus, as is shown in Fig. 6B, the edge A is divided into an edge (A1) having labels $f(S1[j..i-1]) = (002)$ and $f(S2[j..i-1]) = (011)$, and an edge (A2) having labels that are obtained by removing, from the original label, $f(S1[j..i-1])$ and $f(S2[j..i-1])$ (i.e., labels (2003\$) and (1014\$)). At step 210, "YES" is substituted into the flag node#constructed, and program control advances to step 212.

At this time, since the temporary t is ϕ , the decision at step 212 is affirmative, and program control is shifted to step 218. Since the flag node\$constructed indicates "YES," the decision at step 218 is affirmative, and program control advances to step 222. At step 222, a node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ (a node between the edges A1 and A2 in this case) is stored in the temporary t . At step 224, the node stored in the area sL of the parent node (root node V_{root}) of the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is substituted into the parameter s . When the process at step 200 is performed the next time, the search is initiated beginning at the node that is stored in the parameter s .

At step 226, a child node (leaf node) is prepared for the node between the edges A1 and A2. And a label (= (003\$)) that is obtained by removing $f(S1[j..i-1]) = f(S1[2..4]) = (002)$ from $f(S1[j..i]) = f(S1[2..5]) = (002003$)$ (= (003\$)), and a label (= (014\$)) that is obtained by removing $f(S2[j..i-1]) = f(S2[2..4]) = (011)$ from $f(S2[j..i]) = f(S2[2..5]) = (011014$)$ are provided for an edge B between the node between the edges A1 and A2 and the child node.

When the value of the counter j is incremented at step 228, $i = 5$ and $j = 3$ is obtained. Thus, the decision at step 230 is negative, and program control returns to step 200, whereat the structure suffix tree generation process is repeated under the condition wherein $i = 5$ and $j = 3$.

5

Since with $i = 5$ and $j = 3$, $f(S1[j..i-1]) = f(S1[3..4]) = (00)$ and $f(S2[j..i-1]) = f(S2[3..4]) = (01)$, at step 200 the edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is found (edge A1). Further, since $f(S1[j..i]) = f(S1[3..5]) = (000)$ and $f(S2[j..i]) = f(S2[3..5]) = (010)$, the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i])) = \phi$ and the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1])) = \phi$. The decisions at step 202 and 204 are negative, and program control advances to step 208.

10

At step 208, the edge (A1 in this case) of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is divided based on the search results obtained at step 200, and a node that corresponds to $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is prepared. Thus, as is shown in Fig. 6C, the edge A1 is divided into an edge A3 having labels $f(S1[j..i-1]) = (00)$ and $f(S2[j..i-1]) = (01)$, and an edge A4 having labels ((2) and (1)) that are obtained by removing ($f(S1[j..i-1])$ and $f(S2[j..i-1])$) from the original label. At step 210, "YES" is substituted into the flag node#constructed, and program control advances to step 212.

15

20

At this time, since at step 222 the node between the old edge A1 (current edge A4) and the edge A2 is stored in the temporary t , the decision at step 212 is negative and program control advances to step 214. Then, the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ (in this case, the node between the edges A3 and A4) is stored in the area sL of the node that is stored in the temporary t . At step 216, ϕ is substituted into the temporary t , and program control advances to step 218. Since the flag node#constructed indicates "YES," the decision at step 218 is affirmative, and program control advances to step 222.

25

30

At step 222, the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ (the node between the edges A3 and A4 in this case) is stored in the temporary t . At step 224, a node that is stored in

the area sL of the parent node (the root node Vroot) of the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is substituted into the parameter s. When the process at step 200 is performed the next time, the search is initiated beginning at the node that is stored in the parameter s.

5

At step 226, a child node (leaf node) is prepared for the node between the edges A3 and A4. Then, a label (= (003\$)) that is obtained by removing $f(S1[j..i-1]) = f(S1[3..4]) = (00)$ from $f(S1[j..]) = f(S1[3..]) = (00003\$)$, and a label (= (014\$)) that is obtained by removing $f(S2[j..i-1]) = f(S2[3..4]) = (01)$ from $f(S2[j..]) = f(S2[3..]) = (00014\$)$ are provided for an edge C between the node between the edges A3 and A4, and the child node.

10

When the value of the counter j is incremented at step 228, $i = 5$ and $j = 4$, and the decision at step 230 is negative. Program control thereafter returns to step 200, whereat the structure suffix tree generation process is repeated under the condition wherein $i = 5$ and $j = 4$.

15

Since, with $i = 5$ and $j = 4$, $f(S1[j..i-1]) = f(S1[4]) = (0)$ and $f(S2[j..i-1]) = f(S2[4]) = (0)$, at step 200 an edge A3 of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is found. Further, since $f(S1[j..i]) = f(S1[4..5]) = (00)$ and $f(S2[j..i]) = f(S2[4..5]) = (00)$, the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i])) = \phi$ and the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1])) = \phi$. Thus, the decisions at steps 202 and 204 are negative, and program control advances to step 208.

20

At step 208, the edge (A3 in this case) of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is divided based on the search results obtained at step 200, and a node that corresponds to $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is prepared. Thus, as is shown in Fig. 6D, the edge A3 is divided into an edge A5 for which labels $f(S1[j..i-1]) = (0)$ and $f(S2[j..i-1]) = (0)$, and an edge A6 for which labels (i.e., (0) and (1)) that are obtained by removing $f(S1[j..i-1])$ and $f(S2[j..i-1])$ from the original label. At step 210, "YES" is substituted into the flag node#constructed, and program control thereafter advances to step 212.

25

30

At this time, since at step 222 the node between the old edge A3 (current edge A6) and the edge A4 is stored in the temporary t, the decision at step 212 is negative, and program control advances to step 214. The node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ (the node between the edges A5 and A6 in this case) is stored in the area sL of the node that is stored in the temporary t. At step 216, ϕ is substituted into the temporary t, and program control advances to step 218. Since the flag node#constructed indicates "YES," the decision at step 218 is affirmative, and program control thereafter advances to step 222.

At step 222, the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ (the node between the edges A5 and A6) is stored in the temporary t. At step 224, a node that is stored in the area sL of the parent node (root node Vroot in this case) of the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is substituted into the parameter s. When the process at step 200 is performed the next time, the search is initiated beginning at the node that is stored in the parameter s.

At step 226, a child node (leaf node) is prepared for the node between the edges A5 and A6. And a label (= (003\$)) that is obtained by removing $f(S1[j..i-1]) = f(S1[4]) = (0)$ from $f(S1[j..]) = f(S1[4..]) = (0003\$)$ and a label (= (010\$)) that is obtained by removing $f(S2[j..i-1]) = (f(S2[4]) = (0))$ from $f(S2[j..]) = f(S2[4..]) = (0010\$)$ are provided for an edge D between the node between the edges A5 and A6 and the child node.

When the value of the counter j is incremented at step 228, $i = 5$ and $j = 5$, and the decision at step 230 is negative. Program control then returns to step 200, whereat the structure suffix tree generation process is repeated under the condition wherein $i = 5$ and $j = 5$.

While with $i = j = 5$, $S1[j..i-1]$ and $S2[j..i-1] = \phi$ and the edge of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1])) = \phi$, $S1[j..i] = S1[5] = (0)$ and $S2[j..i] = S2[5] = (0)$, so that the edge (A5) of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is present. Thus, the decision at step 202 is affirmative, and program control is shifted to step 232. The parent node (the root node Vroot) of the

edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is substituted into the parameter s . When the process at step 200 is performed the next time, the search is initiated beginning at the node that is stored in the parameter s .

- 5 At step 234, a check is performed to determine whether the temporary t is ϕ . Since at step 222 the node between the edges $A5$ and $A6$ is stored in the temporary t , the decision at step 234 is negative, and program control advances to step 236. The node (the root node V_{root} in this case) that has been substituted into the parameter s is stored in the area sL of the node that is stored in the temporary t . At step 238, ϕ is substituted into the
- 10 temporary t , and the structure suffix tree generation process is temporarily halted. When the value of the counter i is incremented, the structure suffix tree generation process is resumed under the condition wherein $i = 6$ and $j = 5$.

- Since with $i = 6$ and $j = 5$, $f(S1[j..i-1]) = f(S1[5]) = (0)$ and $f(S2[j..i-1]) = f(S2[5]) = (0)$,
- 15 at step 200 the edge ($A5$) of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is found. Further, since $S1[j..i] = S1[5..6] = (00)$ and $S2[j..i] = S2[5..6] = (01)$, the edge ($A6$) of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ also exists. Therefore, the decision at step 202 is affirmative, and program control is shifted to step 232. The parent node (the node between the edges $A5$ and $A6$ in this case) of the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is substituted into the parameter s .
- 20 When the process at step 200 is performed the next time, the search is initiated beginning at the node that is stored in the parameter s .

- Further, since ϕ is substituted into the temporary t , the decision at step 234 is affirmative, and the structure suffix tree generation process is temporarily halted. When the value of
- 25 the counter i is incremented, the structure suffix tree generation process is resumed under the condition wherein $i = 7$ and $j = 5$.

- Since, with $i = 7$ and $j = 5$, $f(S1[j..i-1]) = f(S1[5..6]) = (00)$ and $f(S2[j..i-1]) = f(S2[5..6]) = (01)$, at step 200 the edge ($A6$) of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is found. Further,
- 30 since $S1[j..i] = S1[5..7] = (000)$ and $S2[j..i] = S2[5..7] = (010)$, the edge C of $E(f(S1[j..i]))$

and $E(f(S2[j..i]))$ is also present. Therefore, the decision at step 202 is affirmative, and program control is shifted to step 232. The parent node (the node between the edges A6 and C in this case) of the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i]))$ is substituted into the parameter s. When the process at step 200 is performed the next time, the search is initiated beginning at the node that is stored in the parameter s.

Since ϕ is substituted into the temporary t, the decision at step 234 is affirmative, and the structure suffix tree generation process is temporarily halted. When the value of the counter i is incremented, the structure suffix tree generation process is resumed under the condition wherein $i = 8$ and $j = 5$.

Since with $i = 8$ and $j = 5$, $f(S1[j..i-1]) = f(S1[5..7]) = (000)$ and $f(S2[j..i-1]) = f(S2[5..7]) = (010)$, at step 200 the edge C of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is found. Furthermore, since $f(S1[j..i]) = f(S1[5..8]) = (000\$)$ and $f(S2[j..i]) = f(S2[5..8]) = (010\$)$, the edge of $E(f(S1[j..i]))$ and $E(f(S2[j..i])) = \phi$, and the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1])) = \phi$. Thus, the decisions at steps 202 and 204 are negative, and program control advances to step 208.

At step 208, the edge (edge C in this case) of $E(f(S1[j..i-1]))$ and $E(f(S2[j..i-1]))$ is divided, and a node that corresponds to $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is prepared. Thus, as is shown in Fig. 6E, the edge C is divided into an edge C1 having labels of $f(S1[j..i-1]) = (0)$ and $f(S2[j..i-1]) = (0)$, and an edge C2 having labels $((03\$)$ and $(14\$))$ that are obtained by removing $f(S1[j..i-1])$ and $f(S2[j..i-1])$ from the original label. At step 210, "YES" is substituted into the flag node#constructed, and program control advances to step 212.

Since the temporary t is ϕ at this time, the decision at step 212 is affirmative, and program control is shifted to step 218. Since the flag node#constructed indicates "YES," the decision at step 218 is affirmative, and program control advances to step 222. At step 222, the node (the node between the edges C1 and C2 in this case) of $V(f(S1[j..i-1]))$ and

V(f(S2[j..i-1])) is stored in the temporary t. At step 224, a node that is stored in the area sL of the parent node (the node between the edges A6 and C1 in this case) of the node of V(f(S1[j..i-1])) and V(f(S2[j..i-1])) is substituted into the parameter s. When the process at step 200 is performed the next time, the search is initiated beginning at the node that is stored in the parameter s.

At step 226, a child node (leaf node) is prepared for the node between the edges C1 and C2. Then, a label (= (\$)) that is obtained by removing f(S1[j..i-1]) = f(S1[5..7]) = (000) from f(S1[j..]) = f(S1[5..]) = (000\$), and a label (= (\$)) that is obtained by removing f(S2[j..i-1]) = f(S2[5..7]) = (010) from f(S2[j..]) = f(S2[5..]) = (010\$) are provided for an edge E between the node between the edges C1 and C2 and the child node. Through the above processing, for a range of j = 1 to 5, the suffixes f(S1[j..]) and f(S2[j..]) of the first character string S1 and the second character string S2 are built in the structure suffix tree.

A brief explanation will now be given as for the range wherein j = 6. For suffixes f(S1[6..]) = (00\$) and f(S2[6..]) = (00\$), as is shown in Fig. 6F, an edge D is divided into an edge D1 having labels of f(S1[j..i-1]) = f(S1[6]) = (0) and f(S2[j..i-1]) = f(S2[6]) = (0), and an edge D2 having labels (03\$) and (10\$) that are obtained by removing f(S1[j..i-1]) and f(S2[j..i-1]) from the original label. A child node is prepared between the edges D1 and D2. And a label (= (\$)) that is obtained by removing f(S1[j..i-1]) = f(S1[6..7]) = (00) from f(S1[j..]) = f(S1[6..]) = (00\$) and a label (= (\$)) that is obtained by removing f(S2[j..i-1]) = f(S2[6..7]) = (00) from f(S2[j..]) = f(S2[6..]) = (000\$) are provided for an edge F between the node between the edges D1 and D2 and the child node. As a result, the suffixes f(S1[6..]) = (00\$) and f(S2[6..]) = (00\$) are assembled into the structure suffix tree.

For suffixes f(S1[7..]) = (0\$) and f(S2[7..]) = (0\$), as is shown in Fig. 6G, a child node is prepared between the edges A5 and A6. And a label (= (\$)) that is obtained by removing f(S1[j..i-1]) = f(S1[7]) = (0) from f(S1[j..]) = f(S1[7..]) = (0\$) and a label (= (\$)) that is obtained by removing f(S2[j..i-1]) = f(S2[7]) = (0) from f(S2[j..]) = f(S2[7..]) = (0\$) are

provided for an edge G between the node between the edges A5 and A6 and the child node. As a result, the suffixes $f(S1[7..]) = (0\$)$ and $f(S2[7..]) = (0\$)$ are assembled into the structure suffix tree.

- 5 Further, for suffixes $f(S1[8]) = (\$)$ and $f(S2[8]) = (\$)$, as is shown in Fig. 6H, a child node is prepared for the root node. And a label of $f(S1[j..]) = f(S1[8]) = (\$)$ ($f(S1[j..i-1]) = \phi$) and a label of $f(S2[j..]) = f(S2[8]) = (\$)$ ($f(S2[j..i-1]) = \phi$) are provided for an edge H between the root node and the child node. As a result, the suffixes $f(S1[8]) = (\$)$ and $f(S2[8]) = (\$)$ are assembled into the structure suffix tree.

10

To make it easier to understand the structure suffix tree generation processing, an explanation has been given by employing a character string S that is much shorter than a character string that will actually be processed. Therefore, it is difficult to say that the area sL and the temporary t will function effectively. However, as the length of the character string and the scale of the suffix tree to be generated are increased, the area sL and the temporary t function more effectively, and the search at step 200 begins at a lower node based on the information stored in the area sL and the temporary t. Therefore, the time required to search for a node and to generate a structure suffix tree can be considerably reduced.

15

20

When the structure suffix tree for the target character string S is generated in the above described manner, the value of the counter i exceeds the value n, and the decision at step 110 is affirmative. The structure suffix tree generation processing is thereafter terminated.

25

An explanation will now be given for the analyzation of the structure of the character string S by using the structure suffix tree of the character string S (when the character string S represents a base array, the analyzation of the structure of the character string S is equivalent to the analyzation of the structure of the base array). The following

processing is also implemented by the structure analyzation program that is installed in the computer system 10.

Sequences that are present in a single-stranded DNA base array or an RNA base array
5 and that have the same structure tend to have similar functions. And when identical
sequences or sequences that, even though their appearances differ, have the same
structure appear frequently, the sequences may acquire a three-dimensional structure that
induces an important function. Therefore, for the analyzation of genetic information, it is
very important that sequences that have the same structure and that frequently appear in a
10 single-stranded DNA base array or an RNA base array, including those sequences that
have the same structure but that have different appearances, are regarded and extracted as
identical sequences. On the other hand, through the following simple process, for which
the structure suffix tree is used, all the character sequences that frequently appear in a
character string S can be extracted, including the character sequences that have the same
15 structure but that have different appearances.

That is, in the structure suffix tree, when a specific node V includes i leaf nodes as
descendants (all the nodes present toward leaves as viewed from the node V), i character
sequences of label(V) are present in the character string S (the same thing is applicable
20 for the suffix tree). Therefore, a sequence that has a length of at least m and that appears
at least i times can be extracted by searching all the nodes of the suffix tree that have at
least i leaf nodes as descendants.

The above search method is the same as the method employed when frequently appearing
25 character sequences are extracted from the suffix tree. When the structure suffix tree of
the invention is employed for the search, all the sequences, including those that have the
same structure but that have different appearances, can be extracted.

For the analyzation of genetic information, in addition to the above described extraction
30 of frequently appearing sequences, it is also extremely important that the sequences that

are present in the two base arrays be regarded and extracted as sequences having the same structure, regardless of whether these sequences have the same appearance. On the other hand, by employing the following simple process that uses the structure suffix tree, all the common character sequences that are present in the character string pair can be extracted, including the sequences that have the same structure but have different appearances.

Specifically, initially the character strings S1 and S2 (the first target array and the second target array), from which a common character sequence is to be extracted, are coupled together and the following character string S is obtained.

$S = S1 + '$1' + S2 + '$2'$ where + denotes coupling, \$1 denotes a first end identification character (first identification data), and \$2 denotes a second end identification character (second identification data). Then, the above described structure suffix tree generation process (the calculations performed for prev(S) and compl(S) and the generation of a structure suffix tree) is performed for the character string S that is employed as a processing target.

For the thus structured suffix tree, if a specific node V other than a leaf node has as descendants a leaf node V1 whose label(V) includes \$1 and a leaf node V2 whose label(V2) does not include \$1, it can be ascertained that the label(V) is a character sequence common to the character strings S1 and S2. Therefore, all the nodes that match the above condition are searched for and extracted from the structure suffix tree, so that all the character sequences common to the character strings S1 and S2 are extracted, including the sequences that have the same structure but have different appearances.

Through the calculations performed for prev(S) and compl(S) using the character string S, the first character string S1 and the second character string S2 that are obtained are regarded as a single pair of corresponding character strings, and a structure suffix tree is prepared wherein a label that corresponds to the character sequence of the first character string S1 and a label that corresponds to the character sequence of the second character

string S2 are provided for the individual edges. Another method may also be used to generate the suffix tree.

Specifically, after the first character string S1 and the second character string S2 are obtained by performing the $\text{prev}(S)$ and $\text{compl}(S)$ calculations, all the "0"s that are present in one (defined as a character string A) of the character strings S1 and S2 are replaced with numerical values for which the signs of numerical values that are present at the same positions as the "0"s are inverted. Or, the character string may be replaced in accordance with an algorithm for directly changing the target character string into a character string that is obtained using the above described replacement process. Then, a single character string that is obtained may be employed to generate a structure suffix. In this case, since the amount of data for the character string that is provided as a label for each edge can be reduced, a smaller memory capacity will be required for the storage of the structure suffix tree.

Further, in the structure suffix tree generation process in Fig. 5, each time a new node other than a leaf node is generated (step 208) (i.e., each time "YES" is substituted into the flag node#constructed), the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ is stored in the temporary t (step 222). Then, when the structure suffix tree generation process is performed the next time, the node of $V(f(S1[j..i-1]))$ and $V(f(S2[j..i-1]))$ (step 214), or a node that is substituted into the parameter s (step 236), is stored in the area sL of the node that is stored in the temporary t. The stored node is employed at step 200 to determine a node whereby the search for an edge is to be initiated. The invention, however, is not limited to this process, and a set T (with ϕ as the initial value) of nodes may be set for each edge of the structure suffix tree, and a node may be stored in the area sL by using the set T as follows.

Specifically, each time a new node other than a leaf node is prepared (step 208), all the nodes of the set $T(e_0)$ that corresponds to the edge (e_0) of $E(f(S1[j..i-1]))$ and $E(f(S1[j..i-1]))$ are sorted in accordance with whether the value obtained by adding one to the length

of the corresponding label is smaller than "i-2" or is greater than "i-1." Assume that of the two edges acquired by the edge division at step 208, an edge near the root node Vroot is defined as an edge e1, and an edge farther from the root node Vroot is defined as an edge e2. Of the nodes belonging to the set T(e0), the node whose label is ascertained to be shorter than "i-2" is allocated to the set T(e1) of the edge e1, while the node whose label is ascertained to be longer than "i-1" is allocated to the set T(e2) of the edge e2. For all the nodes v that are allocated to the set T(e2), the node of V(f(S1[j..i-1])) and V(f(S2[j..i-1])) is stored in the area sL(v). Then, at step 236, the node that is substituted into the parameter s is stored in the area sL of the node that is stored in the temporary t, and following this, the node that is stored in the temporary t is added to the set T(E(f(S1[j..i-1])) and E(f(S1[j..i-1]))).

Through the above processing, although the structure suffix tree generation process is slightly complicated, the search at step 200 can be initiated at a lower node, and the time required to search for a node and to generate a structure suffix tree can be further reduced.

The analyzation of the structure of a target array has been explained by using a character string that can be obtained by replacing the elements of the array with other characters. In this embodiment, arbitrary data can be used to replace the elements of the array, and an arbitrary data string that represents the target array can be employed to analyze the structure of the target array.

In the above description, the present invention has been applied for the analyzation of the structure of a DNA base array and an RNA base array. However, the present invention is not limited to such analyzations, and can also be applied for the analyzation of a similar polymer array structure.

In addition, in the above explanation, the structure analyzation program that carries out the array conversion method and the structure analyzation method of the invention is

originally stored on the data storage medium 60, which is the storage medium that is employed in accordance with the present invention. Further, when the program on the data storage medium 60 is installed in the computer system 10 and executed, the computer system 10 functions as the structure analyzation apparatus of the invention.

- 5 However, another mode may be employed. That is, the structure analyzation program may be retained in the storage device of another information processing apparatus (e.g., a network server) that is connected, across a computer network (e.g., a LAN, the Internet or a wireless communication network), to the computer system 10 via a public line or a communication medium (an optical fiber or a wireless line). When the computer system
- 10 10 communicates with the information processing apparatus, the program is transmitted from the information processing apparatus via the communication medium (the transmission medium of the invention) to the computer system 10. Then, the computer system 10 installs the received program in storage means, such as the HDD 40, and executes it, and can thus function as the structure analyzation apparatus of the present
- 15 invention.

The experiments conducted by the present inventor will now be described.

[First Embodiment]

- 20 The following are all the HIV (Human Immunodeficiency Virus) RNA arrays (accession numbers of arrays: K03455; length: 9719).

25 Of the 73 patterns that were found in the course of the application of the first embodiment, 22 patterns were repetitive patterns, which generally were found to have a common suffix tree, while the remaining 51 patterns were patterns that it was doubtful would have been discovered had the present invention not been employed.

30 [Second Embodiment]

Using the same arrays as those used for the first embodiment, the present inventor employed the present invention to conduct an experiment in which a search was conducted for all the patterns that had a length of at least 8 and that appeared at least 7 times. The search results are shown below.

=== 1st pattern: length = 8

15 [Third Embodiment]

The following are arrays (access number: SA16SRRNA, length: 1334) for the 16S portion of Streptococcus anginosus bacteria.

For the above arrays, the present inventor employed the present invention to conduct an
 experiment in which a search was conducted for all the patterns that had a length of at
 least 10 and that appeared at least two times. The search results are shown below. Since
 10 the arrays searched for in the third embodiment were shorter than those in the first or the
 second embodiment, a reduced number of patterns were found.

=== 1st pattern: length = 10
 131: GGACCTGCGT 370: AAGTTCATAC
 === 2nd pattern: length = 10
 15 97: ATGCTTGAAA 438: CGTAGGTCCC
 === 3rd pattern: length = 11
 280: GGGAACCCTGA 536: TTTGGAAACTG
 === 4th pattern: length = 10
 29: CCTATTAGAG 630: AAGCGGCTCT
 20 === 5th pattern: length = 10
 739: TCCTTTCCGG 985: GTTGGGTAA
 === 6th pattern: length = 10
 527: ATTGTAGGCT 1206: ATTGTAGGCT
 === 7th pattern: length = 10
 25 118: ATCGCTAGTA 1240: ATCGCTAGTA

As is described above, according to the present invention, for a variable in a target array
 that can be replaced by another element in the array, information is substituted that
 indicates the location of a different variable that forms a complementary pair with the
 30 variable that can be replaced, or, for a variable in the target array for which no different,
 complementary variable is available, information is substituted indicating that no such
 variable is available. Since to change an array this process is performed for all the

variables therein, the present invention can provide an excellent effect by so altering an array that its structure can be efficiently analyzed.

Further, according to the present invention, for a variable in a target array that can be replaced by another element, information is substituted that indicates the location of a like variable, or, for a variable in the target array for which a like variable is not available, information is substituted indicating that no like variable is available in order to change the target array into a first array.

Furthermore, for a variable in a target array that can be replaced by another element, information is substituted that indicates the location of a different variable that forms a complementary pair with the variable that can be replaced, or, for a variable in the target array for which a different, complementary variable is not available, information is substituted indicating that no such variable is available in order to change the target array into a second array. Then, since the first and the second arrays are employed to analyze the structure of the target array, the present invention can provide an excellent effect whereby the structure of the target array can be efficiently analyzed.

While the invention has been particularly shown and described with respect to preferred embodiments thereof, it will be understood by those skilled in the art that the foregoing and other changes in form and details may be made therein without departing from the spirit and scope of the invention.
